Технические характеристики на биоактивные малые молекулы, реагенты для анализа быстрого лигирования КОМПАНИИ **Sigma-Aldrich**

Формы антител: аффинные изолированные антитела, очищенные иммуноглобулины.

Structural Genomics Consortium

In your research, it is essential to ensure that your target is the right target. We have partnered with the Structural Genomics Consortium (SGC) to provide highly characterized, novel chemical probes for researching clinically relevant protein targets. These probes, developed and characterized by the SGC, meet strict criteria for potency, selectivity, and cell-permeability in order to be used as essential tools in preclinical target validation. Originally focusing on proteins involved in epigenetic control, including well-studied targets such as the bromodomain-containing BET family of proteins and histone methyltransferase EZH2, the SGC has expanded to include chemical probes for other research areas, including kinases, serine proteases and other protein families.

CHEMICAL PROBES

The SGC is a non-profit organization that partners public and private entities with the goal of conducting open-access research with relevance to drug discovery, placing a primary focus on elucidating the 3D structures of human protein and human parasite protein targets. Approximately 200 scientists from the Universities of Oxford and Toronto and nine pharmaceutical companies work to achieve this goal, making the structures, reagents and methods available to the public to facilitate further research on protein targets.

TARGET VALIDATION USING CHEMICAL PROBES

Backed by full characterization data from the SGC and the consistency and high quality of our Bioactive Small Molecule portfolio, SGC chemical probes allow you to validate your target with confidence. Explore the full offering of SGC chemical probes, including probes for bromodomains, methyltransferases, kinases, and other epigenetic targets.

Duolink[®] Proximity Ligation Assay

Duolink[®] Proximity Ligation Assays (PLA) enable the studying of endogenous Protein-Protein Interactions (PPI) and Post-Translational Modifications, providing a fluorescent signal for a single event that can be visualized by either microscopy or flow cytometry. To study Protein-Protein Interactions, Duolink[®] PLA technology uses a pair of antibodies labeled with oligonucleotides which when present within 40 nm undertake rolling circle amplification to generate a specific fluorescent signal after the addition of labeled probes.

Available in four different colors, for both flow cytometry and microscopy, Duolink[®] PLA allow for the visualization of multiple Protein-Protein Interactions per cell. Uncover the opportunities your research with amplified performance and the benefits of Duolink[®] PLA technology:

- **Visualize protein interactions** – both stable and transient
- **Visualize post-translational modifications**
- **Detect endogenous proteins** – no overexpression or genetic manipulation
- **High specificity** – use of two antibodies/probes eliminates false positives
- **No special equipment needed** – standard immunofluorescence and flow cytometry-based methods available
